ABSTRACT

Several commuter rail systems are beginning to accept mobile payments, in which tickets are purchased and validated on smartphones. Mobile payments may improve the rider experience while reducing costs and simplifying the fare collection process for rail operators. Before investing in this new ticketing technology, rail operators want to understand rider demand for mobile tickets. To assess the potential adoption of mobile payments, stated preference data from an onboard survey on two MBTA Commuter Rail lines (Worcester and Newburyport/Rockport) in the greater Boston area were analyzed. Binary logit was then used to forecast adoption on all commuter rail lines. Based on this model, 26% of Commuter Rail riders in Boston are very likely to adopt mobile ticketing.
INTRODUCTION

Commuter rail services typically use conductor-validated or proof-of-payment fare collection systems. In conductor-validated schemes, such as Boston’s Commuter Rail, riders either prepay or buy tickets from conductors onboard. To prepay, passengers purchase tickets at windows, vending machines, or local retailers. Passengers then present tickets to conductors onboard trains for validation. In proof-of-purchase systems, riders must carry a valid ticket with them and are subject to random inspection (1). Typically, these two types of fare collection are used in barrier-free rail systems.

While these types of fare collection are common in suburban commuter rail services, there are a few noteworthy drawbacks. First, it can be expensive to install equipment and operate the ticketing facilities needed in rail stations for prepayment. Second, ticket windows and onboard fare collection typically involve a large number of cash transactions. This can inconvenience customers who prefer credit or debit payments, particularly if electronic payments are not accepted at ticket windows or onboard trains. There are also significant risks associated with operators handling high volumes of cash, such as theft or fraud.

Although many heavy rail systems in urban centers have transitioned to smartcard fare collection systems (1, 2, 3, 4), most suburban commuter rail networks do not accept contactless smartcard payments. One reason for this is high cost projections in ungated rail systems; this includes installing gates or validation systems and maintaining fare equipment distributed over extensive geographic areas. Additionally, installing a smartcard system—particularly with barriers—involve a significant change in customer experience for most conductor-validated or proof-of-payment fare collection systems. For these reasons and others, commuter rail operators have struggled to adopt smartcard fare collection systems.

As an alternative strategy, many commuter rail operators are now considering mobile payments for fare collection. Mobile payments would enable riders to purchase tickets directly on their smartphones with a credit card, debit card, or other electronic payment. This option may improve the customer experience by replacing prepayment at ticket windows or vending machines, which typically require some amount of waiting in line, thereby saving travel time. Furthermore, mobile payment with credit and debit cards can help reduce the number of cash transactions at ticket windows and onboard trains. Finally, mobile purchases may provide rail operators with valuable planning data that are currently not available in cash-based systems (i.e. disaggregate origin and destination information). In light of these advantages, several commuter rail systems are beginning to implement mobile payments.

OBJECTIVE

Given this interest in mobile payments, this research aims to assess the level of demand for mobile payments by commuter rail riders. Stated preference survey data from two Commuter Rail lines in the greater Boston area are used in a discrete choice modeling framework to predict mobile payment adoption by riders. This model is then used to forecast demand for mobile payments on the entirety of Boston’s Commuter Rail network.

Since most commuter rail operators do not yet accept mobile payments, there is limited information about the potential size of the market. Therefore, this study investigates consumer demand for this new payment option and forecasts adoption on a large suburban rail network. The proposed methodology and corresponding results may inform regional rail operators who are interested in mobile payments but have not conducted detailed customer research.
BACKGROUND ON MOBILE PAYMENTS

Mobile payments enable riders to purchase tickets directly on their smartphones using a credit card, debit card, or other electronic payment. This transaction occurs in real-time over a cellular network and is then processed like a standard credit or debit transaction. Passengers may be required to activate their ticket before it is valid for travel. Operators then have several validation options, such as visually inspecting the smartphone ticketing screen or scanning a ticketing barcode with a handheld device. This model of validation for mobile payments is applicable to commuter rail systems that rely on conductor-validated or proof-of-payment fare collection schemes.

Several commuter rail systems in the United States are moving toward mobile ticketing, and they are in different stages of assessment, procurement, testing, and implementation. Long Island Rail Road (LIRR) recently conducted a pilot program in which passengers could purchase mobile tickets for travel to a golf tournament, and they reported that approximately 20% of riders used mobile tickets to travel to the event (5). Metro North Railroad (MNR) in New York and Connecticut is testing mobile tickets with railroad staff (6), and Virginia Railway Express (VRE) in northern Virginia is in a procurement process for mobile ticketing (7). Last, several transit agencies with proof-of-payment fare collection systems are also considering mobile payments, including TriMet in Portland (8) and DART in Dallas (9).

Despite the interest in mobile ticketing by regional rail operators throughout the country, there is very little literature pertaining to mobile payments for commuter rail fare collection. Most prior research has focused on mobile payments utilizing near field communications (NFC) technology and its application to urban bus and subway systems (10, 11, 12). Consequently, additional research could provide significant insight for commuter rail operators considering mobile ticketing systems, and the following analysis begins to fill this gap in the literature.

BACKGROUND ON THE COMMUTER RAIL IN BOSTON

This study analyzes the new mobile ticketing pilot program on the Commuter Rail in Boston (13). The Commuter Rail is operated by the Massachusetts Bay Commuter Rail Company (MBCR) under contract with the Massachusetts Bay Transportation Authority (MBTA) (14). This operation includes fixed schedule, daily service on fourteen heavy rail lines serving downtown Boston via two central city stations (North Station and South Station). It is the fifth largest commuter rail system in the United States based on the number of unlinked passenger trips (15).

Boston’s Commuter Rail has a zone-based fare policy, and both period passes (monthly) and pay-per-ride (single or multi-ride) tickets are available (16). Fare collection is administered through a conductor-validated system. Riders can prepay for tickets in rail stations at vending machines or at ticket windows, although many outlying stations lack ticketing facilities. Commuting riders can also purchase tickets through pre-tax employer programs, with participating companies in greater Boston distributing tickets directly to corporate program customers. Once onboard, conductors validate single and multi-ride tickets using a hole-punch, and monthly passes are simply shown to the conductor as a flash pass. Passengers also have the option of purchasing single ride tickets from the conductor onboard with cash at a higher price (16).

In late 2006, the MBTA launched the CharlieCard smartcard and magnetic stripe fare collection system on MBTA buses, subway, and light rail (17). The only part of the CharlieCard system that integrates with Commuter Rail are monthly passes; the backside of the Commuter
Rail flash pass has a magnetic stripe ticket that can be used for free transfers onto MBTA subway trains and buses.

Over the past six years, there has been significant interest in expanding the CharlieCard system to Commuter Rail (18). Due to various constraints – most importantly, cost – this has not happened. The MBTA originally invested more than $150 million in the CharlieCard system for subway, bus, and light rail. When proposals for expansion to the Commuter Rail estimated over $70 million in costs, the MBTA chose to pursue an alternative strategy.

In early 2012, the MBTA announced a one year pilot program for mobile ticketing on the Commuter Rail. This program has minimal upfront costs; instead, the company contracted to provide the mobile ticketing platform will receive 2.8 percent of ticket sales (13). The pilot program officially launched in November 2012, and Commuter Rail riders on all lines traveling into North Station are now able to purchase single- and multi-ride tickets on Android and iPhone smartphones. Before the end of 2012, the pilot will be expanded to include all Commuter Rail lines that operate out of South Station. The MBTA has also announced plans to expand the ticketing options to include monthly passes, as well as create an application for BlackBerry smartphones over the course of the one year pilot program (13).

Riders who participate in the pilot program can purchase mobile tickets for their selected journey (see left screen in Figure 1) using a credit or debit card (see middle screen in Figure 1). Riders then activate their ticket before boarding, and once onboard, conductors can validate mobile tickets by visually inspecting them (see right screen in Figure 1). For further validation, tickets include a barcode that can be used for random scanning to ensure fare compliance.

![Figure 1 Demonstration Screenshots of Commuter Rail Mobile Ticketing Application](image-url)
While the MBTA was planning the mobile ticketing pilot program, they worked in coordination with researchers (authors Brakewood and Rojas) to conduct detailed customer research about the potential adoption of mobile ticketing in Boston, which is described in the following paragraphs.

DATA COLLECTION

The authors and a small group of graduate students conducted a short onboard survey to collect data for this analysis. An onboard sampling method was selected to ensure that only those in the target population (Commuter Rail riders) were reached. The survey was administered on three weekdays in mid-June during the AM and PM peak periods (approximately 6:30-10am and 4-7:30pm). Because ridership on the Commuter Rail is highly peaked in the commuting direction (inbound in the AM, outbound in the PM), the off-peak direction (outbound in the AM, inbound in the PM) was also sampled so both peak and off-peak riders could be included in the analysis. A total of twelve different train trips were sampled; six were outbound trips and six were inbound trips. Once onboard the trains, teams of two to three distributed paper surveys to as many riders as possible.

Line Selection

Due to manpower constraints, all fourteen Commuter Rail lines could not be sampled. Instead, two representative lines were selected for this analysis: the Worcester and Newburyport/Rockport lines (see Figure 2). These lines were selected in order to best represent the population of Commuter Rail riders as a whole. Three factors influenced this selection: geography, ridership levels, and diversity of ridership.

The first factor, geography, was defined based on the terminal stations in downtown Boston. There are two large Commuter Rail stations that serve as the terminus for most Commuter Rail trips (North Station and South Station). Differences in service provision - particularly ticketing facilities at these two locations - could impact adoption of mobile ticketing. The first line that was selected (Newburyport/Rockport) terminates at North Station, and the second line (Worcester) ends at South Station.

Second, only high ridership lines were considered in order to maximize the response rate during the data collection process. Both of the selected lines have average weekday boardings of approximately 17,000 to 18,000 (cumulative counts for the Newburyport and Rockport branches), which makes them two of the highest ridership lines within the overall Commuter Rail network (19).

Third, the diversity of rider income levels and ethnicities from previous survey results (20) were considered. This factor was hypothesized to impact the level of technology adoption and therefore, the potential for mobile ticketing adoption. The Worcester line has relatively high levels of demographic diversity, whereas the Newburyport/Rockport line has a relatively homogenous ridership (20).
Data Collection Constraints

Although standard procedures for survey research were followed, there were a few constraints on the data collection process. First, there was no mail-back option for the survey. Riders were instructed to complete as many questions on the survey as possible during their commute, but some surveys were left incomplete because the rider alighted the train. Additionally, since the survey was only administered in English, a very small number of riders (less than 10) declined participation because they did not speak English. Last, for most of the sampled trips, the data collection process did not extend to the outlying terminal station. There are very few Commuter Rail trips with boardings and alightings between the outermost stations based on previous survey results (20). Therefore, it is reasonable to assume that additional data collection efforts between these stops would not have had a significant impact on the results.
Total Responses

A total of 914 surveys were collected during the fieldwork period, and 903 were deemed sufficiently complete for the following analysis. Sufficient completeness meant that the respondent answered the questions up to and including the stated preference mobile ticketing question (question number 18 on the survey instrument). Table 1 shows the number of completed surveys collected on each line during each time period. The paper surveys results were coded by the authors, and a sample of 5% was cross-checked for any data entry errors.

Survey Content

The survey instrument contained four questions designed to capture topics relevant to the use of mobile ticketing. First, the survey included a question about the adoption of information and communications technologies that could be used to access mobile ticketing applications, particularly smartphones. Second, the utilization of mobile payments for other retail transactions (i.e. Starbucks) was investigated using a revealed preference question. Then, after a brief description of mobile payments on the Commuter Rail, a stated preference survey question was posed to assess the likelihood of participants adopting mobile ticketing. This was followed by a question that probed the respondents’ opinions about mobile payments (i.e. reasons for preferring mobile purchases or not).

STATISTICAL ANALYSIS

A high-level statistical analysis was performed on the four key questions that pertained to mobile ticketing, and the results are summarized in Table 2. This table contains the exact wording used for each of the four questions in the survey instrument, including the description of the stated preference question for mobile ticketing.

As can be seen in Table 2, riders were first asked what devices/technologies they have used in the past 30 days, which included different types of smartphones. This question is crucial to forecasting the potential mobile ticketing market size, since riders without smartphones will be unable to participate in the MBTA’s mobile ticketing initiative. The results show that approximately 76% of riders use smartphones, and the most popular smartphone is the iPhone. As a basis for comparison, approximately 55% of US mobile subscribers own smartphones as of June 2012 (22). These high adoption rates suggest that mobile ticketing is well suited for Commuter Rail.
Next, riders were asked how often they use a smartphone to make purchases (i.e. iTunes, Android Market/Play, Starbucks). Fifty percent of riders make mobile purchases once a month or more. Among the 50% who do not make mobile purchases, almost half do not use smartphones. Then, the survey instrument informed riders that they would be able to purchase and display tickets on their smartphones later this year, and they were asked how likely they are to use their smartphone to buy a Commuter Rail ticket. We received the following answers: 29% of Worcester riders and 25% of Newburyport/Rockport riders indicated that they are very likely to use mobile ticketing. These riders are likely to be early adopters of mobile ticketing. Similarly, 20% of Worcester riders and 18% of Newburyport/Rockport riders indicated that they are somewhat likely to use mobile ticketing, while 22% of Worcester riders and 23% of Newbury/Rockport riders said they were neutral or somewhat unlikely to use mobile ticketing. This second group of riders may eventually use the technology, but it is doubtful that they will be early adopters. Finally, 28% of Worcester riders and 33% of Newburyport/Rockport riders indicated they were very unlikely to use mobile ticketing. Among those respondents who indicated they were unlikely to adopt mobile ticketing, 43% of Newburyport/Rockport riders and 47% of Worcester riders stated that they did not own a smartphone.

Finally, riders were asked how they feel about making mobile purchases on their smartphones, which is intended to gauge rider attitudes towards mobile ticketing. The majority of riders stated that they already make mobile purchases (including those who do not like it) or are open to doing so (55% of Worcester riders and 58% of Newburyport/Rockport riders). Others were worried about making mobile purchases or had never even considered it (20% of Worcester riders and 18% of Newburyport/Rockport riders). These results show that if agencies aim to increase adoption rates, they must consider how to attract this demographic. The remaining 23% of riders on both the Worcester and Newburyport/Rockport lines said they did not have smartphones to make mobile purchases.

One additional caveat should be made about the statistics presented in the previous two paragraphs. All respondents were able to answer the questions pertaining to mobile ticketing for Commuter Rail and their feelings about mobile purchases, regardless of if they currently use a smartphone. There were sixteen respondents (1.7% of 903 total surveys) that said they were “very likely” to use mobile ticketing, but answered the previous question by stating that they had “not used a smartphone in the past thirty days.” While this answer appears to be counterintuitive, six of these respondents had used a Tablet (iPad, Kindle) in the past thirty days, and therefore, they may have assumed that mobile ticketing options would be available on these devices. Additionally, two of these sixteen respondents answered the last question by saying “I do not currently make mobile purchases, but I am open to it.” One possible explanation is that these riders may be considering purchasing a smartphone/tablet in the future - a logical conclusion since the adoption rates of these devices are rapidly growing. Finally, the remaining eight of sixteen respondents may have answered the mobile ticketing question in error, but this is a relatively low error rate for a sample of over nine hundred participants.

FORECASTING ANALYSIS

To estimate the probability that a respondent will choose to adopt mobile ticketing, the survey data were used in a discrete choice modeling framework. This model was then utilized with a sample enumeration forecasting technique to estimate the total percentage of Commuter Rail riders who are likely to adopt mobile ticketing.

Specification and Estimation of the Discrete Choice Model

The first step in this analysis was to specify a discrete choice model. The coefficients of the parameters in the model allow for interpretation of the extent to which socioeconomic characteristics of the respondent relate to choice of mobile ticketing versus existing fare media. This is different from discrete choice models commonly discussed in the transit fare policy literature that are based on ticket price (23, 24). Instead, this modeling framework rests on the assumption that mobile tickets are inherently different from the existing fare media (namely paper tickets). This framework was recently applied to the demand for open payment systems (25, 26).

A binary logit model (27) was specified in which the choice set was those who stated they were “very likely” to use mobile ticketing versus everyone else, who were assumed to continue using existing fare media. This modeling framework was selected because those who responded “very likely” will presumably be early adopters of mobile ticketing, and will therefore have the highest likelihood of participating in the MBTA pilot program during the next year.

The open source software package BIOGEME was utilized for estimation of this discrete choice model (28). The independent variables available for this analysis included socioeconomic and travel characteristics of the respondent, which were selected because they aligned with variables available for the forecasting exercise based on previous system-wide survey results (discussed in the following paragraphs). The data from both sampled lines were pooled for this analysis, and the sample size was reduced from 903 to 651 because many survey participants did not complete the demographic questions (namely income and ethnicity). After assessing multiple specifications using these independent variables, the binary logit specification shown in Table 3 was selected as having the most explanatory power while conforming to the constraints above.

Discussion of the Binary Logit Model

The following conclusions can be drawn from the results of the binary logit model. The negative alternative specific constant (-2.94) for mobile ticketing indicates that, all else being equal, the existing fare medium is the preferred alternative. Additionally, the relatively large magnitude of this constant compared to the other coefficients indicates that there is a high level of unexplained preference between the two alternatives.

The first independent variable, age, demonstrates that individuals below 45 are more likely to adopt mobile ticketing, which is indicated by the positive coefficients of the other age variables. Examining the magnitude of the coefficients reveals that as age increases, the respondent is less likely to use mobile ticketing.

Conversely, the coefficients for household income show that as income increases, the likelihood of using mobile ticketing increases. This is shown by the positive coefficients for income, which has a reference group of the lowest household incomes.

For ethnicity, minority groups are somewhat less likely to use mobile ticketing than Caucasian riders, as demonstrated by their negative coefficients. It should be noted that “Hispanic” was asked separately from ethnicity, and the positive coefficient of the “Hispanic” variable indicates that they are more likely to adopt mobile ticketing than non-Hispanic riders.
Frequency of travel and gender were not statistically significant, as indicated by t-statistics of less than 1.5.

Last, the overall goodness of fit of the model is moderately low. An adjusted rho-squared of 0.160 suggests that the independent variables have a somewhat limited relationship with fare medium intention.

**Forecasting**

After estimating the discrete choice model, a forecasting analysis was conducted using sample enumeration to predict the adoption of mobile ticketing on the entire Commuter Rail network. The data used in the forecasting exercise are from the Central Transportation Planning Staff (CTPS) Commuter Rail survey conducted in 2008-2009 (20). This system-wide survey asked questions pertaining to travel behavior and demographic information needed for the Boston area travel demand model; questions about technology adoption were not asked. Therefore, the forecasting analysis was constrained by the questions available from this system-wide survey.

CTPS provided the authors with the raw data from this system-wide survey for all Commuter Rail questions pertaining to gender, age, ethnicity, household income, and frequency of travel. The total sample size of the CTPS dataset was 12,960 respondents, but this was reduced to 10,407 because some respondents did not answer all of the demographic questions (namely household income). The CTPS dataset included a weight for each respondent to assure system-wide representativeness. Weights were not used in the sample enumeration calculation. Once the sample enumeration was performed, the probability that each rider would use mobile ticketing was then weighted by the original value provided by CTPS, and these weighted probabilities were aggregated to determine the total adoption rate on the Commuter Rail network. **The results of this analysis reveal that approximately 26% of Commuter Rail riders are very likely to adopt mobile ticketing.**

**Modeling Constraints and Areas for Improvement**

This analysis aimed to provide a simple methodology to forecast mobile ticketing adoption. Initially, an ordinal logit specification including all mobile ticketing preference levels was tested, but the goodness-of-fit was extremely low, implying that levels of preference other than “very likely” were not reliable indicators of intention. Therefore, the simple binary logit model was selected for presentation in this paper.

In order to improve this analysis, more sophisticated methodologies could be used. For example, the discrete choice model could include more complicated specifications, such as nesting the stated mobile ticketing intention question within the revealed preference of past mobile purchase behavior. Similarly, a model including revealed preference data about smartphone utilization could help predict mobile ticketing adoption. Such models might add insight into the behavior of riders considering adoption of mobile ticketing, but unfortunately, they would not permit forecasting given the datasets available for this specific analysis. Therefore, the discrete choice methodology presented in this paper should be treated as a simple, baseline forecast for mobile ticketing adoption, and future research should aim to improve the model specification.

Additionally, this modeling approach relies completely on stated preference data about mobile ticketing. Because stated intention does not always align with actual behavior, this
analysis could be improved in the future by combining the dataset with actual adoption
information that could become available over the next year.

Last, this forecasting method assumes that all fare types will be included in the mobile
ticketing pilot program this year; similarly, it assumes that the corresponding fares will not be
raised or lowered. At this time, the pilot program does not include monthly passes, although it is
anticipated that this will be added over the course of the pilot year. Additionally, the pilot
program does not have plans for distribution of tickets purchased through corporate pass
programs. Based on the survey results, approximately 30% of Worcester and 42% of
Newburyport/Rockport riders purchase their tickets through pre-tax employer programs.
Because of this constraint, the actual adoption of mobile ticketing in the Commuter Rail pilot
program is likely to be lower than the forecasted results.

**CONCLUSIONS**

This research demonstrates significant potential for adoption of mobile ticketing on the
Commuter Rail network in Boston. The onboard survey data revealed that there are high levels
of technology usage by riders, with approximately 76% of riders using smartphones and 50%
making mobile purchases at other merchants. Mobile ticketing offers these riders a more
convenient purchase method than prepayment at ticket windows or vending machines and is less
problematic (for both the customer and operator) than onboard cash transactions. Furthermore, it
is a low cost option for the MBTA and other rail operators to capitalize on existing infrastructure
– the widespread adoption of smartphones among their riders – rather than installing gates or
validation systems over extensive geographic areas.

To assess the potential adoption of mobile payments, stated preference data from an
onboard survey on two MBTA Commuter Rail lines in the greater Boston area were analyzed.
Binary logit was used to forecast adoption on the entire rail network, and the results showed that
approximately 26% of all Commuter Rail riders stated that they are likely to adopt mobile
ticketing. Considering the dearth of research about the potential size of the market, this forecast
should help the MBTA and other agencies make informed decisions regarding mobile ticketing.
Moreover, the survey data provided important information concerning rider attitudes towards
adoption of mobile ticketing, offering rail operators additional statistics. In light of this research
and the widespread adoption of smartphones, mobile ticketing appears to be a compelling
alternative to traditional ticketing methods, and its adoption by rail operators and utilization by
riders are likely to increase in the near future.
